

Since this program is an amplitude modulation,

$$\omega = 2\pi f_0 / \text{RATE}$$

$$\theta = \theta + \omega$$

$$\text{output_block}[n] = \text{int}(\text{input_tuple}[n] * \cos(\theta))$$

$$\cos\theta = \frac{1}{2}(e^{j\theta} + e^{-j\theta})$$

So $H(e^{j\omega}) = \frac{1}{2} H(e^{j(\omega-\theta)}) + \frac{1}{2} H(e^{j(\omega+\theta)})$, it is the sum of two signals which have shift compare to the origin. The shift distance is equal to f_0 .

The figures show clear change when input signal is whistle.

- When $f_0 = 400$

- When $f_0 = 200$
